1 Stats 21 - HW 4

1.1 Charles Liu (304804942)

Homework copyright Miles Chen. Problems have been adapted from the exercises in Think Python 2nd Ed by Allen B. Downey.

This is your third homework assignment.

The questions have been entered into this document. You will modify the document by entering your code.

Make sure you run the cell so the requested output is visible. Download the finished document as either a PDF or an HTML file.

You will submit:

- the rendered HTML/PDF file
- this ipynb file with your answers

1.2 Reading

- Chapters 14 to 18

Please keep up with the reading. The chapters are short.

1.2.1 Exercise 15.1

Write a definition for a class named `Circle` with attributes `center` and `radius`, where `center` is a `Point` object and `radius` is a number.

Instantiate a `Circle` object that represents a circle with its center at `(150, 100)` and radius `75`.

Write a function named `point_in_circle` that takes a `Circle` and a `Point` and returns `True` if the `Point` lies in or on the boundary of the circle.

Write a function named `rect_in_circle` that takes a `Circle` and a `Rectangle` and returns `True` if the `Rectangle` lies entirely in or on the boundary of the circle.

Write a function named `rect_circle_overlap` that takes a `Circle` and a `Rectangle` and returns `True` if any of the corners of the `Rectangle` fall inside the circle.

```
[3]: # no need to modify this code
class Point:
```

```

"""Represents a point in 2-D space.
attributes: x, y
"""

def print_point(p):
    print('%g, %g' % (p.x, p.y))

class Rectangle:
    """Represents a rectangle.
    attributes: width, height, corner.
    """

```

```

[4]: import copy
import math

class Circle:
    """represents a circle
    attributes: center, radius"""

def distance_for_two_points(point1, point2):
    distx = point1.x - point2.x
    disty = point1.y - point2.y
    dist_all = math.sqrt(distx**2 + disty**2)
    return dist_all

def point_in_circle(point, circle):
    d = distance_for_two_points(point, circle.center)
    print(d)
    return d <= circle.radius

```

1.2.2 Exercise 16.1

Write a function called `mul_time` that takes a `Time` object and a number and returns a new `Time` object that contains the product of the original `Time` and the number.

```
[6]: # code that defines Time class and some functions needed for 16.1
# no need to modify
class Time:
    """Represents the time of day.

    attributes: hour, minute, second
    """
    def print_time(t):
        """Prints a string representation of the time.

        t: Time object
        """
        print('%02d:%02d:%02d' % (t.hour, t.minute, t.second))
    def int_to_time(seconds):
        """Makes a new Time object.

        seconds: int seconds since midnight.
        """
        time = Time()
        minutes, time.second = divmod(seconds, 60)
        time.hour, time.minute = divmod(minutes, 60)
        return time
    def time_to_int(time):
        """Computes the number of seconds since midnight.

        time: Time object.
        """
```

```

minutes = time.hour * 60 + time.minute
seconds = minutes * 60 + time.second
return seconds

```

```

[7]: # write your function here
def mul_time(time, number):
    time_int = time_to_int(time) * number
    new_time = int_to_time(time_int)
    return new_time

```

```

[8]: # test code:
race_time = Time()
race_time.hour = 1
race_time.minute = 34
race_time.second = 5

print('Half marathon time', end=' ')
print_time(race_time)

distance = 13.1 # miles
pace = mul_time(race_time, 1/distance)

```

Half marathon time 01:34:05

1.3 Exercise 16.2.

The `datetime` module provides time objects that are similar to the `Time` objects in this chapter, but they provide a rich set of methods and operators. Read the documentation at

<https://docs.python.org/3/library/datetime.html>

1. Use the `datetime` module to write a program that gets the current date and prints the day of the week.

```

[9]: import datetime

```

```

[10]: # example usage
new_date = datetime.date(2020, 5, 11)
print(new_date)

```

2020-05-11

```

[22]: today_date = datetime.date.today()
today_day_of_week = today_date.strftime("%A")
print("Date:", today_date, "\n", "Day of the Week:", today_day_of_week)

```

Date: 2020-05-18
Day of the Week: Monday

2. Write a function that takes a birthday as input and prints the user's age and the number of days, hours, minutes and seconds until their next birthday.

```
[89]: # function for time until next birthday
def time_until_next_birthday(date):
    current_bday = datetime.datetime.strptime(date, "%m/%d/%Y")
    today_date = datetime.datetime.today()
    next_bday = current_bday.replace(year = today_date.year)
    if next_bday < today_date:
        next_bday = next_bday.replace(year = today_date.year + 1)
    last_bday = current_bday.replace(year = next_bday.year - 1)
    age = last_bday.year - current_bday.year
    print("User's Age:", end=" ")
    print(age)
    until_next_bday = next_bday - today_date
    days = until_next_bday.days
    (temp, seconds) = divmod(until_next_bday.seconds, 60)
    (hours, minutes) = divmod(temp, 60)
    print("Next Birthday is in:", "%d:%d:%d:%d"%(days, hours, minutes, seconds),
    ↪ "(Days:Hours:Minutes:Seconds)")
```

```
[90]: birthdate = "12/25/1999" # month/day/year
birthdate2 = "3/26/1972"
# print time until next birthday
time_until_next_birthday(birthdate)
time_until_next_birthday(birthdate2)
```

User's Age: 20

Next Birthday is in: 220:13:22:31 (Days:Hours:Minutes:Seconds)

User's Age: 48

Next Birthday is in: 311:13:22:31 (Days:Hours:Minutes:Seconds)

3. For two people born on different days, there is a day when one is twice as old as the other. That's their Double Day. Write a program that takes two birth dates and computes their Double Day.

```
[117]: def double_day(date1, date2):
    # Have to use "datetime.datetime. ..."
    bday1 = datetime.datetime.strptime(date1, "%m/%d/%Y")
    bday2 = datetime.datetime.strptime(date2, "%m/%d/%Y")
    lower_date = min(bday1, bday2)
    upper_date = max(bday1, bday2)
    doubled = (upper_date - lower_date) + upper_date
    print("It's your DOUBLE DAY on!:", doubled, "(Year-Month-Day)", "(Hours:
    ↪ Minutes:Seconds)")
```

```
[118]: # test case
person1 = "12/25/1999"
```

```
person2 = "4/15/1970"
double_day(person1, person2)
```

It's your DOUBLE DAY on!: 2029-09-04 00:00:00 (Year-Month-Day)
(Hours:Minutes:Seconds)

```
[119]: # test case
person1 = "3/26/1972"
person2 = "1/20/1985"
double_day(person1, person2)
```

It's your DOUBLE DAY on!: 1997-11-16 00:00:00 (Year-Month-Day)
(Hours:Minutes:Seconds)

```
[120]: # test case
person1 = "11/9/2001"
person2 = "3/23/2010"
double_day(person1, person2)
```

It's your DOUBLE DAY on!: 2018-08-04 00:00:00 (Year-Month-Day)
(Hours:Minutes:Seconds)

1.4 Exercise 17.1.

I have included the code from chapter 17 Change the attributes of Time to be a single integer representing seconds since midnight. Then modify the methods (and the function `int_to_time`) to work with the new implementation.

You should not have to modify the test code in main. When you are done, the output should be the same as before.

```
[121]: # Leave this code unchanged
class Time:
    def __init__(self, hour=0, minute=0, second=0):
        self.hour = hour
        self.minute = minute
        self.second = second

    def __str__(self):
        return '%.2d:%.2d:%.2d' % (self.hour, self.minute, self.second)

    def print_time(self):
        print(str(self))

    def time_to_int(self):
        minutes = self.hour * 60 + self.minute
        seconds = minutes * 60 + self.second
        return seconds
```

```

def is_after(self, other):
    return self.time_to_int() > other.time_to_int()

def __add__(self, other):
    if isinstance(other, Time):
        return self.add_time(other)
    else:
        return self.increment(other)

def __radd__(self, other):
    return self.__add__(other)

def add_time(self, other):
    assert self.is_valid() and other.is_valid()

```

1.5 Exercise 17.2

This exercise is a cautionary tale about one of the most common, and difficult to find, errors in Python.

We create a definition for a class named `Kangaroo` with the following methods:

1. An **init** method that initializes an attribute named `pouch_contents` to an empty list.
2. A method named **put_in_pouch** that takes an object of any type and adds it to `pouch_contents`.
3. A **str** method that returns a string representation of the `Kangaroo` object and the contents of the pouch.

Test your code by creating two `Kangaroo` objects, assigning them to variables named `kanga` and `roo`, and then adding `roo` to the contents of `kanga`'s pouch.

You don't actually have to write anything for this. Instead, I have included the textbook solutions for these problems.

Read the code in `Badkangaroo.py` and then in `GoodKangaroo.py`, which I have included here.

```
[127]: # `Badkangaroo.py`
class Kangaroo:
    """A Kangaroo is a marsupial."""

    def __init__(self, name, contents=[]):
        """Initialize the pouch contents.

        name: string
        contents: initial pouch contents.
        """
        self.name = name
        self.pouch_contents = contents

    def __str__(self):
        """Return a string representaion of this Kangaroo.
        """
        t = [ self.name + ' has pouch contents:' ]
        for obj in self.pouch_contents:
            s = '    ' + object.__str__(obj)
            t.append(s)
        return '\n'.join(t)

    def put_in_pouch(self, item):
        """Adds a new item to the pouch contents.

        item: object to be added
        """
        self.pouch_contents.append(item)

kanga = Kangaroo('Kanga')
roo = Kangaroo('Roo')
kanga.put_in_pouch('wallet')
```

```
kanga.put_in_pouch('car keys')
roo.put_in_pouch('candy')
kanga.put_in_pouch(roo)

print(kanga)
```

Kanga has pouch contents:

```
'wallet'
'car keys'
'candy'
<__main__.Kangaroo object at 0x000001BE3F659308>
```

```
[128]: print(roo)
```

Roo has pouch contents:

```
'wallet'
'car keys'
'candy'
<__main__.Kangaroo object at 0x000001BE3F659308>
```

```
[129]: # `GoodKangaroo.py`
class Kangaroo:
    """A Kangaroo is a marsupial."""

    def __init__(self, name, contents=[]):
        """Initialize the pouch contents.

        name: string
        contents: initial pouch contents.
        """
        # The problem is the default value for contents.
        # Default values get evaluated ONCE, when the function
        # is defined; they don't get evaluated again when the
        # function is called.

        # In this case that means that when __init__ is defined,
        # [] gets evaluated and contents gets a reference to
        # an empty list.

        # After that, every Kangaroo that gets the default
        # value gets a reference to THE SAME list. If any
        # Kangaroo modifies this shared list, they all see
        # the change.

        # The next version of __init__ shows an idiomatic way
        # to avoid this problem.
        self.name = name
```

```

        self.pouch_contents = contents

def __init__(self, name, contents=None):
    """Initialize the pouch contents.

    name: string
    contents: initial pouch contents.
    """
    # In this version, the default value is None. When
    # __init__ runs, it checks the value of contents and,
    # if necessary, creates a new empty list. That way,
    # every Kangaroo that gets the default value gets a
    # reference to a different list.

    # As a general rule, you should avoid using a mutable
    # object as a default value, unless you really know
    # what you are doing.
    self.name = name
    if contents == None:
        contents = []
    self.pouch_contents = contents

def __str__(self):
    """Return a string representaion of this Kangaroo.
    """
    t = [ self.name + ' has pouch contents:' ]
    for obj in self.pouch_contents:
        s = '    ' + object.__str__(obj)
        t.append(s)
    return '\n'.join(t)

def put_in_pouch(self, item):
    """Adds a new item to the pouch contents.

    item: object to be added
    """
    self.pouch_contents.append(item)

kanga = Kangaroo('Kanga')
roo = Kangaroo('Roo')
kanga.put_in_pouch('wallet')
kanga.put_in_pouch('car keys')
roo.put_in_pouch('candy')
kanga.put_in_pouch(roo)

print(kanga)

```

```
print(roo)
```

Kanga has pouch contents:

```
'wallet'  
'car keys'  
<__main__.Kangaroo object at 0x000001BE3F68D488>
```

Roo has pouch contents:

```
'candy'
```

1.6 Exercise 18.3

The following are the possible hands in poker, in increasing order of value and decreasing order of probability:

- pair: two cards with the same rank
- two pair: two pairs of cards with the same rank
- three of a kind: three cards with the same rank
- straight: five cards with ranks in sequence (aces can be high or low, so Ace-2-3-4-5 is a straight and so is 10-Jack-Queen-King-Ace, but Queen-King-Ace-2-3 is not.)
- flush: five cards with the same suit
- full house: three cards with one rank, two cards with another
- four of a kind: four cards with the same rank
- straight flush: five cards in sequence (as defined above) and with the same suit

The goal of these exercises is to estimate the probability of drawing these various hands.

```
[130]: # no need to change this code block  
## Card.py : A complete version of the Card, Deck and Hand classes  
## in chapter 18.

3. Add methods to class `PokerHand` named `has_pair`, `has_twopair`, etc. that return True or False according to whether or not the hand meets the relevant criteria. Your code should work correctly for “hands” that contain any number of cards (although 5 and 7 are the most common sizes).
4. Write a method named `classify` that figures out the classifications for a hand and creates a list of labels accordingly. For example, a 7-card hand might contain a flush and a pair. It will create an attribute `labels` which is a list `["flush", "pair"]`

```
[133]: class PokerHand(Hand):  
        """Represents a poker hand."""  
  
        all_labels = ['straightflush', 'fourkind', 'fullhouse', 'flush',  
                      'straight', 'threekind', 'twopair', 'pair', 'highcard']  
  
        def make_histograms(self):
